QuestionAnswer What are the key differences between SN1 and SN2 reactions in organic chemistry? SN1 reactions proceed via a two-step mechanism involving carbocation formation and are favored by tertiary substrates and polar protic solvents. They typically result in racemization. SN2 reactions are one-step, involve backside attack, favor primary substrates, and occur more readily in polar aprotic solvents, leading to inversion of configuration. How does resonance stabilization influence the reactivity of conjugated dienes in electrophilic addition reactions? Resonance stabilization in conjugated dienes delocalizes electron density, making the double bonds more reactive toward electrophiles and facilitating reactions like conjugated addition. This stabilization lowers activation energy and can lead to regioselectivity, such as in 1,2- and 1,4-additions. What is the significance of the Diels-Alder reaction in organic synthesis? The Diels-Alder reaction is a powerful cycloaddition process that forms six-membered rings with high stereoselectivity and regioselectivity. It allows for efficient construction of complex cyclic structures from dienes and dienophiles, making it invaluable in synthesizing natural products and pharmaceuticals. How do methyl and other alkyl substituents affect the acidity of phenols and alcohols? Alkyl substituents like methyl groups are electron-donating via hyperconjugation, which decreases the acidity of phenols and alcohols by stabilizing the conjugate base less effectively. Conversely, electron-withdrawing groups increase acidity by stabilizing the conjugate base. What

are the typical mechanisms involved in the oxidation of primary and secondary alcohols? Primary alcohols are oxidized via an initial formation of aldehydes, then further to carboxylic acids, often using reagents like PCC or Jones reagent. Secondary alcohols are oxidized to ketones, typically with reagents such as CrO_3 or PCC. The mechanisms involve hydride transfer and formation of carbonyl intermediates. How does stereochemistry influence the outcome of elimination (E_2) reactions in organic chemistry? In E_2 eliminations, the stereochemistry is crucial; the leaving group and the hydrogen being eliminated must be antiperiplanar (opposite and in the same plane). This requirement affects the stereochemical outcome, often leading to the formation of more stable alkenes, and influences the reaction's regioselectivity and stereoselectivity.
